(Clay Center, Nebraska)

**Richard B. Ferguson**  
University of Nebraska-Lincoln  
(Lincoln, Nebraska)

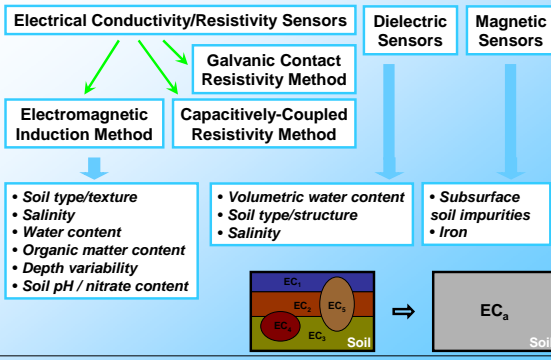

## Problem Statement

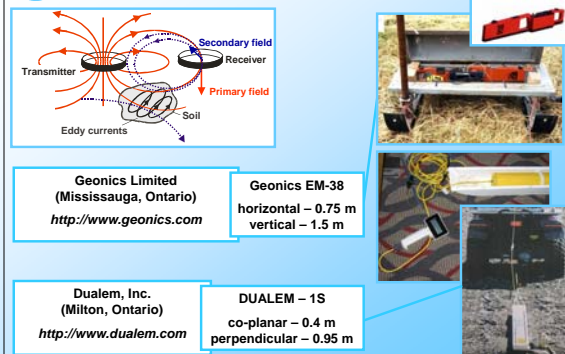

- Soil apparent electrical conductivity ( $EC_a$ ) can be related to a number of properties that affect crop growing conditions
- Soil spatial variability has been evaluated using one or several different  $EC_a$  data layers
- Change of  $EC_a$  with depth can be related to the ability of soil to drain and accumulate water as well as to store nutrients to satisfy crop demand

## Electrical and Electromagnetic Sensors

## Electromagnetic Induction Method

## Vertical Sounding Techniques

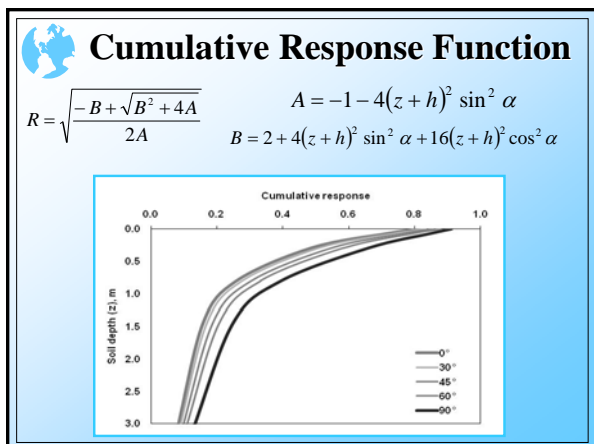

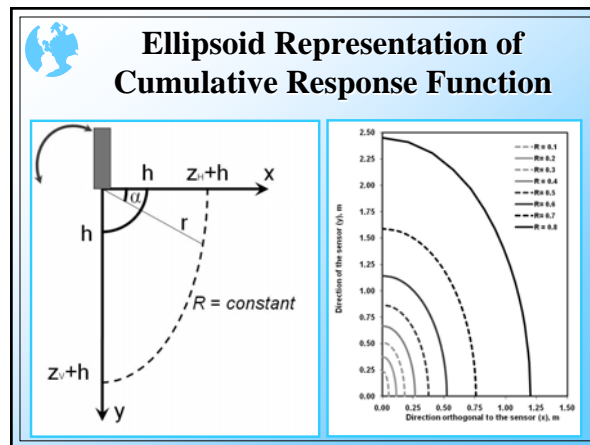

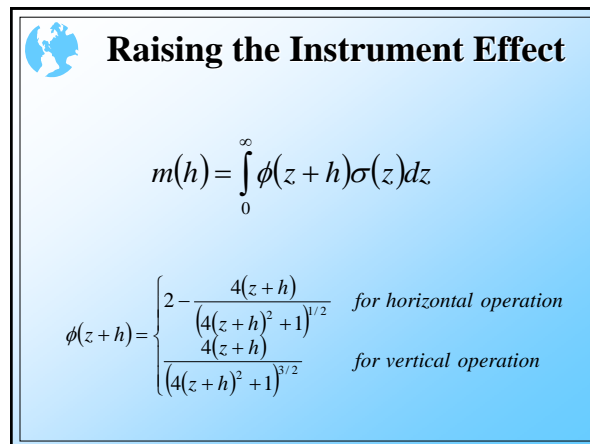

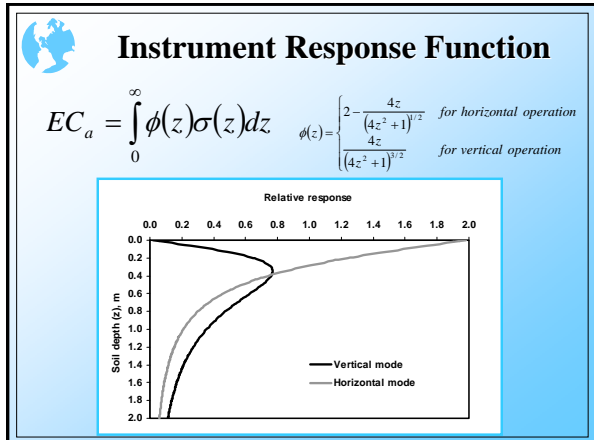

- Using multiple receiving coils at different distances from the transmitting coil
- Using multiple operation frequencies
- Using vertical, horizontal, or hybrid (one coil vertical and one horizontal) modes of operation
- Raising the instrument to different heights above the ground

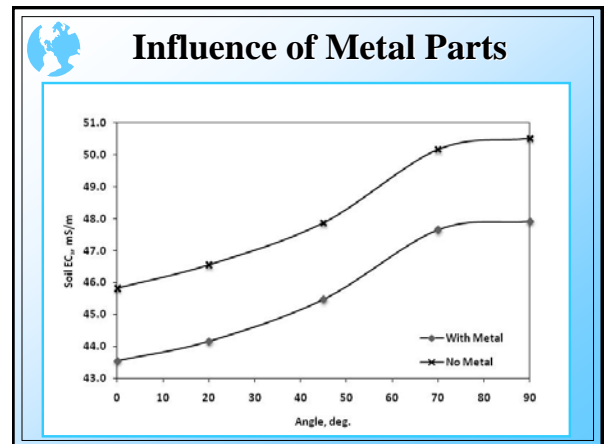

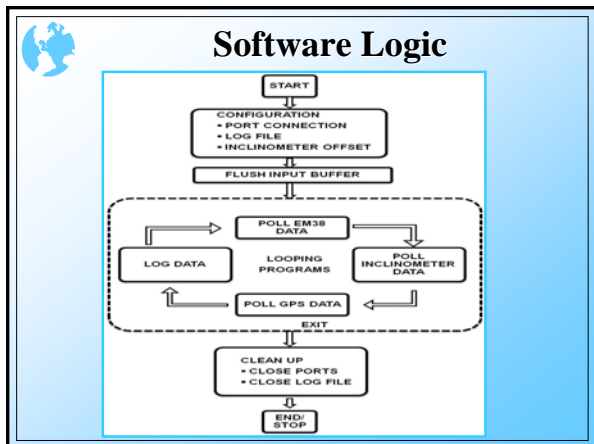

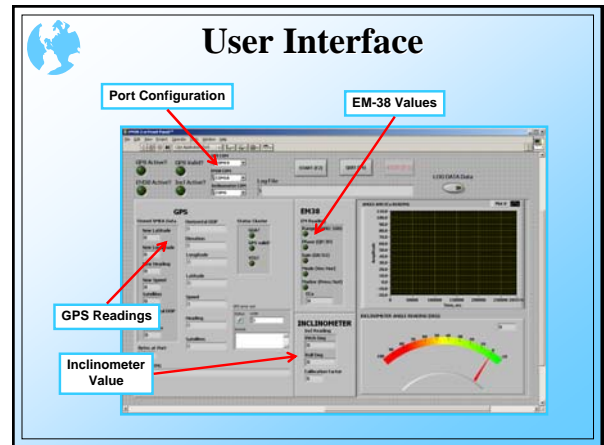

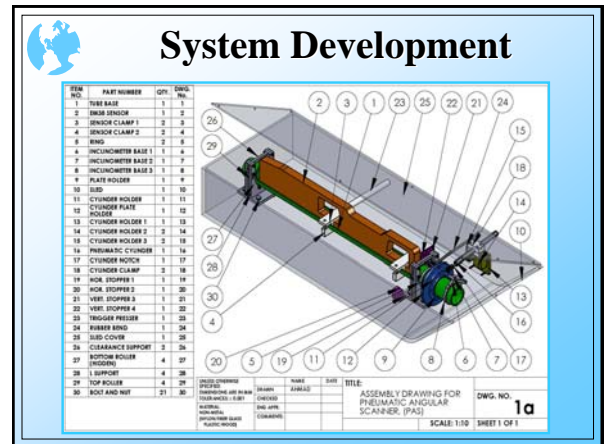

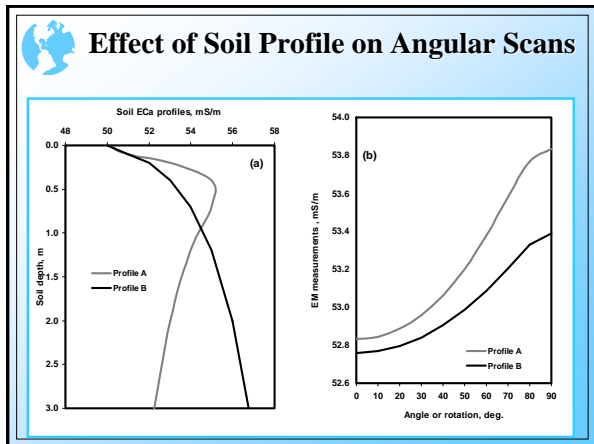

**Angular Scanning**

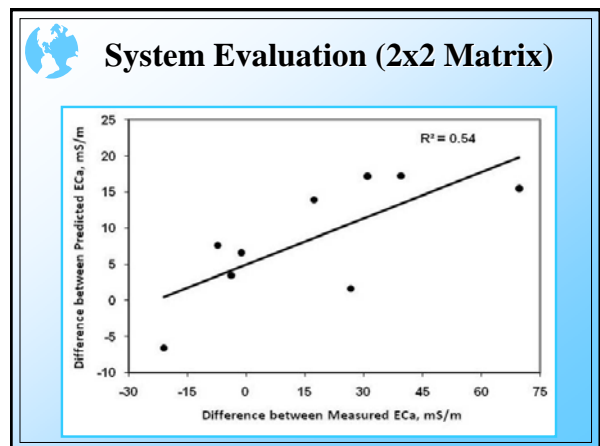

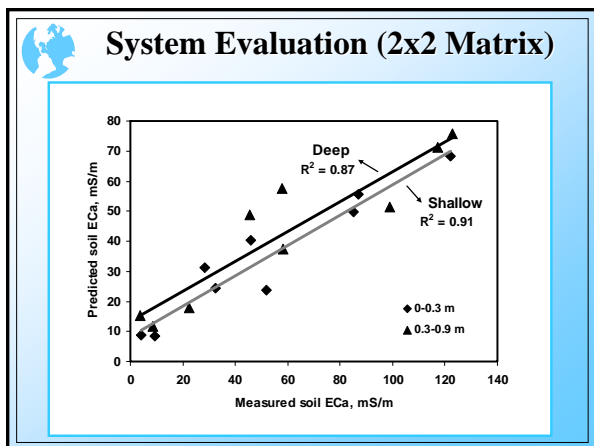

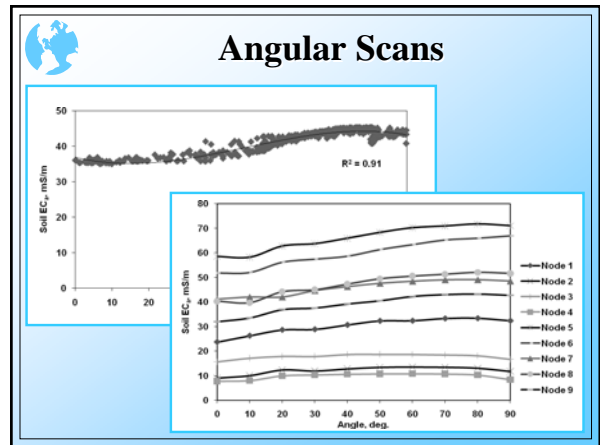

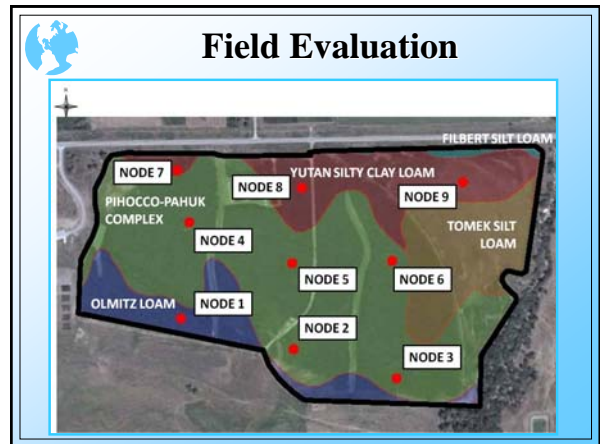

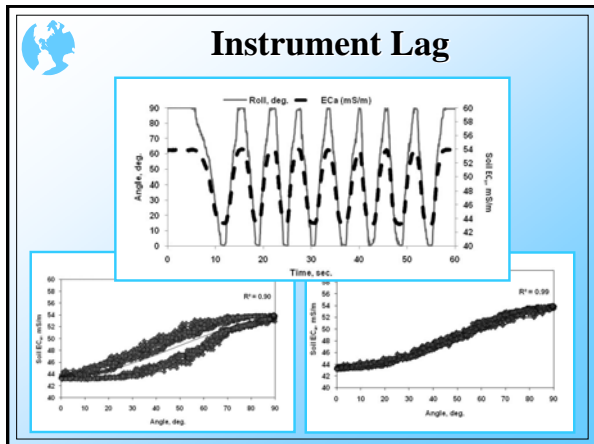

## Research Objectives

- To develop an instrumented platform for an automated angular  $EC_a$  scanning using an electromagnetic induction (EMI) sensor
- To evaluate the system development in a field with different soil  $EC_a$  profiles

## Conclusions

- The Pneumatic Angular Scanning System (PASS) was developed to measure  $EC_a$  when continuously changing the mode of operation of an EMI sensor from vertical to horizontal and back
- At this time, the inversion technique was applied to only two hypothetical soil layers (0-0.3 m and below 0.3 m)
- Development of a more complex inversion solution and stated improvements in the data acquisition process should allow potential users to predict a set of parameters indicating the change of soil  $EC_a$  with depth at each field location, which ultimately would lead to 3-D soil modeling
